What is a data center power flow?

Basic Data Center Power Flow Typically, data centers are set up with several power flow elements: a power source such as a generator, UPS, power distribution unit (PDU), power panel and power whips. Depending on the size of a data center, the power flow may require more than one of the elements.

Why should data center architects consider current and future power requirements?

Data center architects consider current and future power requirements so they can design data centers that aren't under- or over-powered. The use of too much power is expensive and wasteful, while the use of too little power can lead to damaging power surges when workloads spike.

How does a power panel work in a data center?

A power panel, which includes a breaker panel, divides the power it receives from the PDU into circuits. Power whips connect a data center's power panel and equipment power cords to help distribute power evenly and improve power usage effectiveness (PUE). Typical data center power flow elements. ¹ Single-Phase vs. Three-Phase Power

How does a PDU work in a data center?

A PDU takes voltage from the UPS and converts it into a voltage suitable for a data center's power panels and enables power distribution to servers, switches and other equipment. A power panel, which includes a breaker panel, divides the power it receives from the PDU into circuits.
