What is pumped storage hydropower (PSH)?

Pumped storage hydropower (PSH) is a type of hydroelectric energy storage. It is a configuration of two water reservoirs at different elevations that can generate power as water moves down from one to the other (discharge), passing through a turbine. The system also requires power as it pumps water back into the upper reservoir (recharge).

Why is pumped storage hydropower important?

As the global community accelerates its transition toward renewable energy, the importance of reliable energy storage becomes increasingly evident. Among the various technologies available, pumped storage hydropower (PSH) stands out as a cornerstone solution, ensuring grid stability and sustainability.

How does a pumped storage hydropower plant work?

Image from IKM 3D. Pumped storage hydropower facilities rely on two reservoirs at different elevations to store and generate energy. When other power plants generate more electricity than the grid needs, a PSH plant can use that power to pump water into the upper reservoir.

Is hydropower a tapped resource?

Hydropower was America's first renewable power source. It is often mistakenly considered a tapped resource, but according to the U.S. Department of Energy's 2016 Hydropower Vision report, hydropower's capacity can sustainably add 50 new gigawatts by 2050 -- 36 GW of which is pumped storage.
